

**ABSTRACT**

An upper section having a platform for supporting a camera, a lower section having an anchor for mounting into the ground, and an adjustment mechanism for vertically and rotationally adjusting the upper section to selectively aim the camera. In an exemplary embodiment, the adjustment mechanism includes an upper shaft of the upper section and a lower shaft of the lower section being telescopically arranged. For compact storage, the lower section can be inverted and the lower shaft inserted into the upper shaft through an opening in the platform.
